AIA VOICE INSIGHTS

Executive pre-read

Every conversation, remembered

AIA Voice Insights: a debrief assistant for advisors, and a request to run a controlled pilot

For	Details
Readers	Group CEO, CTO, COO, CFO and board members
Read before	The AIA Global Innovation Conference session (about 15 minutes, including a live demo)
Scope	Voice Insights only: the web app (voice-insights-ui) and its API (voice-insights-azureapi)
Status	Draft for review. A working prototype exists. Figures marked as estimates, assumptions or targets are planning inputs, not results.

Decisions we will ask for

- **Approve a controlled pilot** with 10 to 20 advisors, measured against a baseline taken first.
- **Name owners** in Compliance, Legal, Information Security and Data Privacy to review the pilot before and during it.
- **Confirm the environment**: the Azure region and Azure OpenAI quota, and release the advisor group.

1. Summary

After every customer meeting, advisors write notes, complete a fact-find, draft a record of advice, send a follow-up and update the CRM. Most of it depends on memory and spare time. Voice Insights turns the conversation itself into structured insight and draft documents.

Its assistant, **Juno**, works for the advisor and never speaks to the customer. After a meeting the advisor talks, in their own words. Juno says what it understood, asks at most five short questions about what is missing or unclear, and reads it back. The advisor confirms every fact on a sign-off screen. **Only a person can start the analysis or sign off the advice pack.**

A new feature, **Dress Rehearsal**, lets an advisor practise the next meeting against a simulation of the customer they have just debriefed, with a live coach who flags promises and pressure the moment they are said.

The question the pilot answers is simple: does this save advisor time and improve the quality of conversations and records, safely enough to scale?

2. The problem

- **Advisors:** hours go to admin after each meeting, so time that could go to customers goes to typing.
- **Customers:** follow-up is slow and uneven, and what they said can be lost or summarised differently each time. Customers who prefer Mandarin, Malay or Tamil are served less consistently.
- **Compliance:** a promise of returns or an unsuitable comparison is usually found in a file review, long after the conversation. Missing facts are easy to overlook.
- **Leadership:** there is little view of how many conversations happen, how good they are, or how long it takes to move from meeting to advice.

How big each problem is remains a hypothesis until measured. Our planning assumption is about 45 minutes of admin per case. **The pilot starts by measuring the real number** with the advisors who will use the tool.

3. What Voice Insights does

Three ways in

Mode	Who speaks	What the app does
After the meeting	The advisor, earlier	The advisor dictates a summary; the app structures it and shows what a good debrief covers.
With the customer	The advisor, live	Listens to the real conversation, suggests the next question and flags risky statements as they happen.
Debrief with Juno	The advisor, earlier	The advisor dictates freely; Juno checks for gaps, asks at most five questions and reads back.

Debrief with Juno, step by step

- **Dictate.** The advisor briefs Juno the way they would brief a colleague. Juno stays quiet and listens, in English, Mandarin, Malay or Tamil.
- **A live fact-find ledger.** Every fact Juno has appears with the words the advisor used. The ledger shows how much of the 26-field fact-find is captured and what is still open. It is an estimate; the advice pack makes the final count.
- **Juno checks for gaps.** At most five short questions, one at a time, only about what is missing. The advisor can skip at any point.
- **Compliance catch.** If the advisor says a customer will "definitely be approved", Juno raises it, quotes it and offers a compliant way to record it. The flag carries into a conduct note and a clarifying sentence in the follow-up draft.

Sign-off: the advisor takes control

The sign-off screen shows what the advisor said, with names, numbers and risky promises marked where they were spoken. The advisor confirms or fixes each fact in one tap, sees what is still open, and reviews a follow-up message for the customer in four languages. Nothing is sent from the app. One button starts the analysis, and it responds only to a real person.

Dress Rehearsal: practise before it counts

- **Brief.** In under a minute, Juno tells the advisor who they are seeing, what matters to the customer, what the advisor said that needs correcting, and how to open.
- **Rehearse.** Juno plays the customer, using only what the advisor said in the debrief. The advisor answers by voice or by typing. A coach flags promises and pressure the moment they are said.
- **Coach's notes.** What landed, what was missed, risky wording with a better version, and a sentence to open the real meeting with.

It is training only. It is labelled a simulation, nothing from it is saved as a customer record, and nothing is sent to anyone.

What the advisor receives after sign-off

A suggestion analysis from 11 specialist agents (three running in parallel), with evidence from the product documents; an advisory report and customer proposal; and an advice pack of fact-find, record of advice, follow-up messages, CRM note with tasks, and a brief for the next meeting. Leadership gets an admin dashboard of volume, needs, sentiment and compliance flags.

4. Why it is safe to try

Juno used to host the first conversation with the customer. Feedback from the first demo was that when an advisor and an AI host are in the same place, customers may prefer the advisor. We agreed and changed what Juno is for. That one decision removed the highest-risk part of the earlier design: nothing the AI says now reaches a customer.

Control	How it works	Status
Juno speaks only to the advisor	It asks and reads back. It has no channel to the customer.	Built

Control	How it works	Status
No prices, returns or products	Prompt rules, and a wording safety net applied to everything shown.	Built; no automatic output filter yet
"Suggest", never "recommend"	Relevance is shown in words, never a score or percentage, following MAS wording guidance.	Built
Only a person starts the analysis	The button ignores scripted clicks.	Built
Every fact confirmed	The advisor confirms or edits names and numbers on the sign-off screen.	Built
Nothing sent automatically	Follow-ups are drafts; the advisor sends them.	Built
Personal identifiers	ID and card numbers are masked before anything is stored.	Built
Audit trail	Every agent step's input and output is stored.	Built
Formal review	Compliance, Legal, Security and PDPA review of prompts, data flows and retention.	Not yet done. Part of the pilot

These controls work in the prototype and are pilot-grade, not finished. We are not asking the Board to rely on them without review. We are asking for the people who own those risks to review them as part of the pilot.

5. How it is built

Standard parts, chosen so that it scales by adding capacity rather than by redesign.

Layer	Technology
Advisor's browser	React 18 and TypeScript, served from a container
API	Java 21, Spring Boot and Spring AI
Agents	LangGraph4j: 11 specialist agents, three in parallel, each step stored
AI services	Azure OpenAI for speech to text, reasoning, meaning search and Juno's voice
Data	PostgreSQL with pgvector for profiles, analysis runs, advice packs and product-document search; Redis for sessions
Delivery	Docker containers; Azure Container Apps or AKS for the pilot

6. What we know so far

Built and demonstrated

Three capture modes, the Juno debrief with the fact-find ledger, the sign-off screen, Dress Rehearsal, the 11-agent analysis and advice pack, drafts in four languages, and an admin dashboard.

Tested

Scripted spoken debriefs and rehearsals, in English, with a synthetic voice. In those tests Juno caught a deliberately planted promise, the fact-find ledger rose after Juno's questions, and a short debrief reached the sign-off screen in under two minutes. These were short scenarios, so they are a check that the product works, not evidence of time saved in real meetings. Juno and the rehearsal customer answer in roughly 4 to 8 seconds, and a noisy room makes speech recognition less reliable.

Not yet done

- Testing with real advisors and real meetings.
- Native-speaker review of Mandarin, Malay and Tamil wording.
- Formal Compliance, Security and privacy review.
- CRM write-back, and load testing at pilot scale.
- Measured time savings. This needs the baseline first.

7. Value, and how we will measure it

Proposed pilot targets (to be agreed)

Measure	Proposed target
Time from meeting to documented advice	At least 50% lower than the baseline
Follow-up sent within 24 hours	90% of pilot cases
Fact-find fields captured or flagged as missing	At least 80% completeness
Advice packs reviewed and signed off by the advisor	100%. No pack used unsigned
Fact-find completeness with Juno, against dictation alone	Higher, for the same advisors
Advisor satisfaction	4 out of 5 or better
Time to a full suggestion analysis	Under 60 seconds
Running cost per conversation	Under SGD 1

The two debrief modes are recorded separately, so the pilot can compare them directly. If Juno's mode is both faster and more complete, the dictation-only mode can be retired later. If advisors prefer to dictate alone, we keep both.

An illustration of scale (not a forecast)

Input	Example value
Advisors using the tool	200
Cases per advisor per month	8
Admin minutes saved per case	45 (an assumption, to be replaced by the baseline)
Hours returned to customer work each month	1,200, about 7.5 full-time equivalents

What it costs (planning estimates for Finance to confirm)

Item	Estimate
Running one conversation	About SGD 0.35 to 0.60 (public list prices; check against AIA's Azure agreement)
Four-month proof-of-concept planning range	About SGD 241,000 to 350,000, mostly team time
Extra cash if the team is existing AIA staff	About SGD 34,000 to 74,000, including contingency

8. Proposed pilot

Proposed shape, for the pilot owners to confirm.

Phase	Duration	What happens
Baseline and review	2 weeks	Time study with the pilot advisors. Compliance and Privacy review the prompts, wording, consent practice and retention. Targets agreed.
Pilot	8 weeks	10 to 20 advisors use both debrief modes on real cases. Weekly check-ins. Every pack signed off by the advisor.
Evaluate	2 weeks	Results against the targets. A recommendation to scale, adjust or stop.

9. Risks

Risk	Level	How it is handled
AI says something non-compliant (a price, a guarantee)	Lower now	Juno speaks only to the advisor; scripted test pack; Compliance review before the pilot; every output reviewable.
Personal data and consent (PDPA)	High	Privacy assessment, retention rules and advisor-side consent practice agreed with Data Privacy first.
Names and accents misheard	Medium	Every fact confirmed on screen; native-speaker testing for Mandarin, Malay and Tamil.
Slower than dictating	Medium	At most five questions, always skippable; the pilot compares both modes on time and completeness.
Azure capacity or stalls at pilot load	Medium	Request quota early; automatic retries and a second attempt on slow calls; fallback voice.
Advisors do not adopt it	Medium	Involve advisors from the start; measure time saved with them; the advisor stays the decision-maker.

10. What we need from AIA

- An Azure subscription and region approved for the data in scope, with Azure OpenAI quota.
- Product documents and approved wording for the products in the pilot.
- Named contacts in Compliance, Legal, Information Security and Data Privacy.
- A CRM sandbox, if CRM write-back is in scope; and single sign-on details if required.
- Advisor volunteers, and their managers' agreement to take part in the time study and pilot.

Figures marked as estimates, assumptions or targets are planning inputs and should be confirmed with Finance, Compliance and the pilot baseline. Behaviour described as working was observed in the current prototype. Source material: the Voice Insights POC overview, the Debrief with Juno plan and the technical guide in this repository.
